Hook's Law Experiment

Purpose: To measure the spring constant of a spring using two different methods.

Background: If a weight $F = mg$ is hung from the end of an unknown spring, causing it to stretch a distance x from its original and unstrained form, F is related to the spring which opposes the pull of the weight. If F is not so large as to permanently distort the spring, then the force F will restore the spring to its original length after the load is removed. The magnitude of the restoring force is directly proportional to the stretch.

$$F = kx$$

The constant k is called the spring constant. Its significance lies in relation to the change in length of the spring, as in Eq. 1.

$$F = mg = kx \quad (1)$$

In this case it is apparent that if a plot of F vs. distance x from a force position, the gradient confirms that the spring follows Hooke's Law and confirms Eq. 1.

An additional experiment is possible. The difference of simple harmonic motion is that a motion under a force "obeys" Hooke's Law" restoring force. Thus for the simple harmonic motion, the period does not depend upon the amplitude of the oscillation. For such a motion, we have

$$T = 2\pi \sqrt{m/k} \quad (2)$$

which gives us the spring constant. T is the period of the position and m is the mass that is oscillating. Thus, the mass includes the mass of the spring itself. However, the entire spring does not oscillate with the same amplitude as the load (the attached mass) and therefore it is necessary to measure the effective load (not the mass being hung) from the end of the spring plus some fraction of the mass of the spring. Based on earlier experiments, one third of the mass of the spring is a good approximation of the effective load due to the spring, that

$$m_{\text{eff}} = m + \frac{1}{3}m_s$$

where m_s is the effective load of the spring. Using this in Eq. 2, we find

$$T = 2\pi \sqrt{\frac{m + \frac{1}{3}m_s}{k}} \quad (3)$$

The effective load of the mass can be determined by a suitable value under the influence
