

Operon: groups of genes that are regulated together. Since a group of genes with a common function can be transcribed together and a single signal can be used to control whether the genes are actively transcribed or not.

Operon contains a promoter and an operator.

Operator is a region of DNA within the promoter or between the promoter and the genes to be transcribed. When inhibitors are bound to the operator, RNA polymerase cannot transcribe the genes. Operons are found mostly in prokaryotes.

When a **repressor** is attached to the promoter region of DNA, the structural genes needed to synthesize lactose-digesting enzymes are inactive, preventing transcription. When the repressor protein is bound to the DNA, RNA polymerase cannot bind to the DNA. So we need an inducible operon to remove the repressor.
